

Advanced Data Analysis

These are the same subjects measured before (pre_score) and after (post_score) an intervention. Did their scores change significantly?

已停止思考 >

Yes. Because the same subjects were measured before and after the intervention, a **paired-samples t-test** is appropriate.

The analysis showed a statistically significant increase in scores after the intervention:

- Mean pre-score = **48.49**
- Mean post-score = **52.82**
- Mean change = **+4.32 points**

Paired t-test result:

$$t(24) = 2.83, p = 0.009$$

Since the p-value is below 0.05, the difference is statistically significant. The intervention appears to have increased scores.
